I, the undersigned, being an officer duly authorised in accordance with Section 74(1) and (4) of the Deregulation & Contracting Out Act 1994, to sign and issue certificates on behalf of the Comptroller-General, hereby certify that annexed hereto is a true copy of the documents as originally filed in connection with the patent application identified therein.

I also certify that the attached copy of the request for grant of a Patent (Form 1/77) bears an amendment, effected by this office, following a request by the applicant and agreed to by the Comptroller-General.

In accordance with the Patents (Companies Re-registration) Rules 1982, if a company named in this certificate and any accompanying documents has re-registered under the Companies Act 1980 with the same name as that with which it was registered immediately before reregistration save for the substitution as, or inclusion as, the last part of the name of the words "public limited company" or their equivalents in Welsh, references to the name of the company in this certificate and any accompanying documents shall be treated as references to the name with which it is so re-registered.

In accordance with the rules, the words "public limited company" may be replaced by p.l.c., plc, P.L.C. or PLC.

Re-registration under the Companies Act does not constitute a new legal entity but merely subjects the company to certain additional company law rules.

Warning

After an application for a Patent has been filed, the Comptroller of the Patent Office will consider whether publication or communication of the invention should be prohibited or restricted under Section 22 of the Patents Act 1977. You will be informed tf it is necessary to prohibit or restrict your invention in this way. Furthermore, if you live in the United Kingdom, Section 23 of the Patents Act 1977 stops you from applying for a patent abroad without first getting written permission unless an application has been filed at least six weeks beforehand in the United Kingdom for a patent for the same invention and either no direction prohibiting publication or communication has been given, or any such direction has been revoked.

Novel Compounds

This invention relates to newly identified diaminoacid-polyamine:peptide and diaminoacid-aminoacid-polyamine based gemini surfactant compounds, to the use of such compounds and to their production. The invention also relates to the use of the diaminoacid-polyamine:peptide based gemini compounds to facilitate the transfer of compounds into cells for drug delivery.

Surfactants are substances that markedly affect the surface properties of a liquid, even at low concentrations. For example surfactants will significantly reduce surface tension when dissolved in water or aqueous solutions and will reduce interfacial tension between two liquids or a liquid and a solid. This property of surfactant molecules has been widely exploited in industry, particularly in the detergent and oil industries. In the 1970s a new class of surfactant molecule was reported, characterised by two hydrophobic chains with polar heads which are linked by a hydrophobic bridge (Deinega, Y et al., Kolloidn. Zh. 36, 649, 1974). These molecules, which have been termed "gemini" (Menger, FM and Littau, CA, J.Am. Chem. Soc. 113, 1451, 1991), have very desirable properties over their monomeric equivalents. For example they are highly effective in reducing interfacial tension between oil and water based liquids and have a very low critical micelle concentration (Menger, FM and Keiper, JS, Angewandte. Chem. Int. Ed. Engl., 2000, 39, 1906).

Cationic surfactants have been used *inter alia* for the transfection of polynucleotides into cells in culture, and there are examples of such agents available commercially to scientists involved in genetic technologies (for example the reagent TfxTM-50 for the transfection of eukaryotic cells available from Promega Corp. WI, USA).

The efficient delivery of DNA to cells *in vivo*, either for gene therapy or for antisense therapy, has been a major goal for some years. Much attention has concentrated on the use of viruses as delivery vehicles, for example adenoviruses for epithelial cells in the respiratory tract with a view to corrective gene therapy for cystic fibrosis (CF). However, despite some evidence of successful gene transfer in CF patients, the adenovirus route remains problematic due to inflammatory side-effects and limited transient expression of the transferred gene. Several alternative methods for *in vivo* gene delivery have been investigated, including studies using cationic surfactants. Gao,X *et al. Gene Ther*. 2,710-722,1995 demonstrated the feasibility of this approach with a normal human gene for CF transmembrane conductance regulator (CFTR) into the respiratory epithelium of CF mice using amine carrying cationic lipids. This group followed up with a liposomal CF gene therapy trial which, although only partially successful, demonstrated the potential for this approach in humans (Caplen, NJ.

10

15

et al., Nature Medicine, 1, 39-46, 1995). More recently other groups have investigated the potential of other cationic lipids for gene delivery (Miller, A, Angew. Int. Ed. Engl., 37, 1768-1785, 1998), for example cholesterol derivatives (Oudrhiri,N et al. Proc.Natl.Acad.Sci. 94, 1651-1656, 1997). This limited study demonstrated the ability of these cholesterol based compounds to facilitate the transfer of genes into epithelial cells both in vitro and in vivo, thereby lending support to the validity of this general approach.

These studies, and others, show that in this new field of research there is a continuing need to develop novel low-toxicity surfactant molecules to facilitate the effective transfer of polynucleotides into cells both *in vitro* for transfection in cell-based experimentation and *in vivo* for gene therapy and antisense treatments. Gemini surfactants based on cysteine (Camilleri, P. and al., patent WO9929712) or on spermine or diamine (Camilleri, P. and al., patent WO0076954) have already been synthesised probing the usefulness of this approach. The present invention seeks to overcome the difficulties exhibited by existing compounds.

The invention relates to diaminoacid-polyamine:peptide based gemini compounds having a diaminoacid-polyamine or a diaminoacid-aminoacid-polyamine backbone and conforming to the general structure of formula (I):

Compounds of the present invention may be prepared from readily available starting materials using synthetic peptide chemistry well known to the skilled person. The scheme shown in Figure 1 shows a general scheme for the synthesis of the compounds of the invention wherein the hydrocarboxyl groups are linked to the α -amino group of a diaminoacid further linked to a polyamine backbone moiety by amide bonds, the scheme shown in Figure 2 shows a general scheme for the synthesis of the compounds of the invention wherein the hydrocarboxyl groups are linked to the terminal amino group of a diaminoacid further linked to a polyamine backbone moiety by amide bonds and the scheme shown in Figure 3 shows a general scheme for the synthesis of diaminoacid-aminoacid-polyamine:peptide based gemini compounds wherein an aminoacid is linked by an amide bond to the

10

15

20

amino group (α or terminal) of a diaminoacid further linked to a polyamine moiety by an amide bond.

Another aspect of the invention relates to methods for using the diaminoacid-polyamine:peptide based gemini compounds. Such uses include facilitating the transfer of oligonucleotides and polynucleotides into cells for antisense, gene therapy and genetic immunisation (for the generation of antibodies) in whole organisms. Other uses include employing the compounds of the invention to facilitate the transfection of polynucleotides into cells in culture when such transfer is required, in, for example, gene expression studies and antisense control experiments among others. The polynucleotides can be mixed with the compounds, added to the cells and incubated to allow polynucleotide uptake. After further incubation the cells can be assayed for the phenotypic trait afforded by the transfected DNA, or the levels of mRNA expressed from said DNA can be determined by Northern blotting or by using PCR-based quantitation methods for example the Taqman® method (Perkin Elmer, Connecticut, USA). Compounds of the invention offer a significant improvement, typically between 3 and 6 fold, in the efficiency of cellular uptake of DNA in cells in culture, compared with compounds in the previous art. In the transfection protocol, the gemini compound may be used in combination with one or more supplements to increase the efficiency of transfection. Such supplements may be selected from, for example:

- (i) a neutral carrier, for example dioleyl phosphatidylethanolamine (DOPE) (Farhood, H., et al (1985) Biochim. Biophys. Acta, 1235-1289);
- (ii) a complexing reagent, for example the commercially available PLUS reagent (Life Technologies Inc. Maryland, USA) or peptides, such as polylysine or polyornithine peptides or peptides comprising primarily, but not exclusively, basic amino acids such as lysine, ornithine and/or arginine. The list above is not intended to be exhaustive and other supplements that increase the efficiency of transfection are taken to fall within the scope of the invention.

In still another aspect, the invention relates to the transfer of genetic material in gene therapy using the compounds of the invention.

Yet another aspect of the invention relates to methods to effect the delivery of non-nucleotide based drug compounds into cells *in vitro* and *in vivo* using the compounds of the invention.

The following definitions are provided to facilitate understanding of certain terms used frequently herein.

10 .

15

20

"Amino acid" refers to dipolar ions (zwitterions) of the form +H₃NCH®CO₂. They are differentiated by the nature of the group R, and when R is different from hydrogen can also be asymmetric, forming D and L families. There are 20 naturally occurring amino acids where the R group can be, for example, non-polar (e.g. alanine, leucine, phenylalanine) or polar (e.g. glutamic acid, histidine, arginine and lysine). In the case of un-natural amino acids R can be any other group which is not found in the amino acids found in nature.

"Polynucleotide" generally refers to any polyribonucleotide or polydeoxribonucleotide, which may be unmodified RNA or DNA or modified RNA or DNA. "Polynucleotides" include, without limitation single- and double-stranded DNA, DNA that is a mixture of single- and double-stranded regions, single- and double-stranded RNA, and RNA that is mixture of single- and double-stranded regions, hybrid molecules comprising DNA and RNA that may be single-stranded or, more typically, double-stranded or a mixture of single- and double-stranded regions. In addition, "polynucleotide" refers to triple-stranded regions comprising RNA or DNA or both RNA and DNA. The term polynucleotide also includes DNA's or RNA's containing one or more modified bases and DNA's or RNA's with backbones modified for stability or for other reasons. "Modified" bases include, for example, tritylated bases and unusual bases such as inosine. A variety of modifications have been made to DNA and RNA; thus, "polynucleotide" embraces chemically, enzymatically or metabolically modified forms of polynucleotides as typically found in nature, as well as the chemical forms of DNA and RNA characteristic of viruses and cells. "Polynucleotide" also embraces relatively short polynucleotides, often referred to as oligonucleotides.

"Transfection" refers to the introduction of polynucleotides into cells in culture using methods involving the modification of the cell membrane either by chemical or physical means. Such methods are described in, for example, Sambrook et al., MOLECULAR CLONING: A LABORATORY MANUAL, 2nd Ed., Cold Spring Harbor Laboratory Press, Cold Spring Harbor, N.Y. (1989). The polynucleotides may be linear or circular, single-stranded or double-stranded and may include elements controlling replication of the polynucleotide or expression of homologous or heterologous genes which may comprise part of the polynucleotide.

The invention will now be described by way of the following examples.

Example 24. Transfection of recombinant plasmid expressing luciferase into cells using lysine-polyamine-based gemini compounds.

Transfection studies were performed using the adherent cell line CHO-K1 (Puck et al. 1958). Complete medium consisted of MEM alpha medium supplemented with 10 % v/v foetal bovine serum and 1x L-Glutamine. All media and supplements were obtained from Life Technologies.

Stable transfected cell lines expressing β -galactosidase were generated by cotransfection of the plasmid pSV- β -Galactosidase Control Vector (Promega) with the plasmid Selecta Vecta-Neo (R & D Systems) in a 10:1 ratio. Following G418 (Life Technologies) selection (0.8 mg ml⁻¹), candidate cell lines were tested for β -galactosidase activity (β -Gal Reporter Gene Assay, chemiluminescent; Roche Diagnostics).

In Vitro Gene Transfection.

Cells were seeded into 96-well MTP plates (Nunc) 16-18 hours prior to transfection at an approximate density of 1 x 10⁴ cells per well. For transfection, 0.064 µg of the luciferase reporter gene plasmid, pGL3-Control Vector (Promega) per well, was incubated with various concentrations

10

of the diaminoacid-polyamine:peptide-based gemini compounds and complexing agents in a final volume of 100 μ l. After 30 minutes incubation at RT, OPTI-MEM® medium (Life Technologies) was added to the transfection mixture and the solution placed on the cells (final volume per well: 100 μ l). Following a 3 hour or over night incubation at 37°C, the transfection solution was replaced with complete medium and the cells incubated further at 37°C. Reporter gene assays were performed according to the manufacturer's guidelines (Roche Diagnostics) approximately 48 hours post transfection. Luminescence was measured in a Packard TopCount NXT Microplate Scintillation and Luminescence Counter. For normalisation purpose, β -galactosidase activity (β -Gal Reporter Gene Assay, chemiluminescent; Roche Diagnostics) was measured and luciferase activity per β -galactosidase activity was calculated.

11. The compound GSC 157 of formula:

10 12. The compound GSC170 of formula:

13. The compound GSC 184 of formula:

14. The compound GSC101 of formula:

- 15. The use of a diaminoacid-polyamine:peptide-based gemini compound as defined in any one of claims 1 to 14 in enabling transfection of DNA or RNA or analogues thereof into a eukaryotic or prokaryotic cell *in vivo* or *in vitro*.
- 16. The use of a diaminoacid-polyamine:peptide-based gemini compound according to claim 15 wherein the compound is used in combination with one or more supplements selected from the group consisting of:
- 15 (i) a neutral carrier; or

- (ii) a complexing reagent.
- 17. The use according to claim 16 wherein the neutral carrier is dioleyl phosphatidylethanolamine (DOPE).
- 18. The use according to claim 17 wherein the complexing reagent is PLUS reagent.
- 19. The use according to claim 18 wherein the complexing reagent is a peptide comprising mainly basic amino acids.
- 20. The use according to claim 19 wherein the peptide consists of basic amino acids.

20

- 21. The use according to claim 19 or 20 wherein the basic amino acids are selected from lysine and arginine.
- 5 22. The use according to claim 20 wherein the peptide is polylysine or polyornithine.
 - 23. A method of transfecting polynucleotides into cells in vivo for gene therapy, which method comprises administering diaminoacid-polyamine:peptide-based gemini compounds of any one of claims 1 to 22 together with, or separately from, the gene therapy vector.
 - 24. The use of a diaminoacid-polyamine-based gemini compound of any one of claims 1 to 14 to facilitate the transfer of a polynucleotide or an anti-infective compounds into prokaryotic or eukaryotic organism for use in anti-infective therapy.
- 25. The use of a diaminoacid-polyamine-based gemini compound of any one of claims 1 to 14 to facilitate the adhesion of cells in culture to each other or to a solid or semi-solid surface.
 - 32. A process for preparing diaminoacid-polyamine-based gemini compounds of claim 1 or 2 which process comprises the coupling of a succinimidate ester of a diaminoacid linked to its α or terminal amino group to an hydrocarboxyl chain to a polyamine linker using potassium carbonate as a base in a mixture of tetrahydrofuran and water as solvents.

Abstract

Diaminoacid-polyamine:peptide-based gemini compounds are disclosed. The compounds are based on diaminoacid-polyamine or diaminoacid-aminoacid-polyamine backbone with peptide groups and optionally hydrocarboxyl groups linked thereto. Uses of the Diaminoacid-polyamine:peptide-based gemini compounds and methods for their production are also disclosed.
